Exploring the use of Facebook demographics as regional health indicators
Mugur V. Geana, MD, PhD

Premises: A short study* published in the December 2, 2011 issue of Science highlights the value of social networks in promoting weight loss. According to the study, participants who were paired with “friends” with similar interests were more likely to take part in healthy behaviors. Similar findings were suggested by the study I conducted over the summer with diabetic patients from rural Kansas engaged in dedicated social networks. Although social media has seen an explosive evolution over the last years, limited research has been done on its value as a community health or health outcomes indicator. The introduction of Facebook Ads, as well as its targeting engine, provides a unique opportunity to extract data to explore possible correlations between regional Facebook use and major health indicators in which peer-to-peer interaction and support could play a significant role.

Research idea: Explore if declared interest in health and well-being, as well as in outdoor activities correlates with obesity indicators at state level.

Method: Facebook Ads was used to retrieve data regarding total number of Facebook users as well as the number of users that have stated an interest in health and well-being (IHW), and in outdoor activities (IOA). Obesity prevalence data was retrieved from the CDC. Microsoft Map Point was used to map the data and IBM SPSS to perform the statistical analysis.

Results: On November 30, 2011, Facebook had over 139.5 million users in the United States. Of these, about 11.5 million uses (8.19%) stated on their profile that they have an IHW and over 22 million (15.8%) state that they have an interest in IOA. The state-level prevalence of IHW users in the Facebook population is presented in Figure 1. The minimum level recorded was 6.29% (Louisiana); the maximum level was 12.15% (Vermont), with a US mean of 8.82%. For IOA users, the average was 17.56%; minimum was 10.79% (District of Columbia), and maximum was 24.66% (Montana). State-level obesity prevalence in adults 18 years and older, according to 2010 CDC data, is mapped in Figure 2. The mean value for the United States was 27%; Colorado recorded the lowest level at 21%, while Mississippi recorded the highest level of obesity at 24% of the population. Percentage of IHW users was strongly correlated with obesity prevalence, r(50) = -.460, p<.001; no correlation was observed between percentage of IOA users and obesity rates: r(50) = -.214, P>.05.

Discussion: The correlation observed in the present analysis between declared IHW users and obesity rates at state level suggests that selected Facebook demographics may have the potential to become dynamic markers of health indicators at macrosocial level. Further studies need to address the many limitations of this anecdotal finding.
